

Question 12.13.3.1

Anupama Kulshreshtha
EE22BTECH11009

For a loaded die, the probabilities of outcomes are given as under: $\Pr(1) = \Pr(2) = 0.2, \Pr(3) = \Pr(5) = \Pr(6) = 0.1$ and $\Pr(4) = 0.3$

The die is thrown two times. Let A and B be the events, 'same number each time', and 'a total score is 10 or more', respectively. Determine whether or not A and B are independent.

Solution: Let X, Y and Z be random variables with definition given as under:

X	Number appearing on dice the first time
Y	Number appearing on dice the second time
Z	Sum of the numbers appearing on the dice

Table 1: Definition of Random variables.

Let A be the event $X = Y$

$A = ((1, 1), (2, 2), (3, 3), (4, 4), (5, 5), (6, 6))$

We know,

$$\Pr(A) = \sum_{k=1}^6 \Pr(k)^2 \quad (1)$$

$$= 0.2 \times 0.2 + 0.2 \times 0.2 + 0.1 \times 0.1 + 0.3 \times 0.3 + 0.1 \times 0.1 + 0.1 \times 0.1 \quad (2)$$

$$= 0.2 \quad (3)$$

Let B be the event $Z \geq 10$

$B = ((4, 6), (5, 5), (6, 4), (5, 6), (6, 5), (6, 6))$

We know,

$$\Pr(Z = n) = \sum_{k=(n-6)}^6 \Pr(k) \Pr(n - k) \quad (4)$$

$$\implies \Pr(Z = 10) = 0.07 \quad (5)$$

$$\implies \Pr(Z = 11) = 0.02 \quad (6)$$

$$\implies \Pr(Z = 12) = 0.01 \quad (7)$$

Hence,

$$\Pr(B) = \Pr(Z = 10) + \Pr(Z = 11) + \Pr(Z = 12) \quad (8)$$

$$= 0.1 \quad (9)$$

Now, A and B will be independent if,

$$\Pr(A \cap B) = \Pr(A) \Pr(B) \quad (10)$$

$$A \cap B = ((5, 5), (6, 6)) \quad (11)$$

$$\Pr(A \cap B) = 0.1 \times 0.1 + 0.1 \times 0.1 \quad (12)$$

$$= 0.02 \quad (13)$$

$$= \Pr(A) \Pr(B) \quad (14)$$

Hence, events A and B are independent.
